# ADTS

# **Concepts of Programming Languages Lecture 8**

#### Announcements

- » Quiz is next week on Tuesday in-class
- » You should have gotten an email if you have accommodations or conflicts. If you have not, please talk to us immediately
- » Hope you all saw the mock quiz. The actual
  quiz should be easier.

#### Practice Problem

Practice Problem

on 
$$\phi \vdash \text{fun } x \rightarrow \text{match } x \text{ with } | (a, b) \rightarrow a + b : \tau$$

Determine the type  $\tau$  so that the above judgment is derivable from the rules below. Also give a derivation

$$\frac{\Gamma \vdash p : \tau_1 * \ldots * \tau_n \qquad \Gamma, x_1 : \tau_1, \ldots, x_n : \tau_n \vdash e : \tau}{\Gamma \vdash \mathsf{match} \ p \ \mathsf{with} \ | \ x_1, \ldots, x_n \to e : \tau} \ (\mathsf{matchTuple}) \qquad \frac{\Gamma \vdash e_1 : \mathsf{int} \qquad \Gamma \vdash e_2 : \mathsf{int}}{\Gamma \vdash e_1 + e_2 : \mathsf{int}} \ (\mathsf{addInt})$$

$$\frac{\Gamma, x : \tau_1 \vdash e : \tau_2}{\Gamma \vdash \text{fun } x \to e : \tau_1 \to \tau_2} \text{ (fun)} \qquad \frac{(v : \tau) \in \Gamma}{\Gamma \vdash v : \tau} \text{ (va}$$

#### Solution

Let 
$$D=2x:intaxint, a:int,$$
  
b:int?

## Did you do this?

- » Define formal syntax rules for records
- » Define formal typing rules for records
- >> Define formal semantics rules for records

#### Outline

- » Introduce algebraic data types (ADTs) for creating data with given "shapes"
- » Cover parametric and recursive ADTs for more general data structures
- » Lots of examples today!

# Unions

**Second Greatest Feature of OCaml** 

## Simple Variants

```
type os = BSD | Linux | MacOS | Windows
```

A **simple variant** is a *user-defined* type for values of a fixed collection of possibilities

First letter of type names is **lower\_case** and Constructor names is **Upper\_case** 

## Simple Variants

```
type os = BSD | Linux | MacOS | Windows
```

A **simple variant** is a *user-defined* type for values of a fixed collection of possibilities

First letter of type names is **lower\_case** and Constructor names is **Upper\_case** 

## Pattern Matching

```
let supported (sys : os) : bool =
  match sys with
    | BSD -> false
    | _ -> true
```

We work with variants by pattern matching:

» giving a <u>pattern</u> that a value can <u>match</u> with

>> writing what to do for each pattern

## Pattern Matching

We work with variants by pattern matching:

» giving a <u>pattern</u> that a value can <u>match</u> with

>> writing what to do for each pattern

## Data-Carrying Variants

Variants can carry data, which allows us to represent more complex structures

## Data-Carrying Variants

```
type linux distro = Arch | Fedora | NixOS | Ubuntu
           type os
             = BSD of int * int
             Linux of linux distro * int
            MacOS of int
Note the syntax | Windows of int
           let supported (sys : os) : bool =
             match sys with
             BSD (major, minor) -> major > 2 && minor > 3
             -> true
```

Variants can carry data, which allows us to represent more complex structures

#### Practice Problem

```
let area (s : shape) =
  match s with
  | Rect r -> r.base *. r.height
  | Triangle { sides = (a, b) ; angle } -> Float.sin angle *. a *. b
  | Circle r -> r *. r *. Float.pi
```

Define the variant **shape** which makes this function type-check

# What about variable length data?

# Recursive ADTs

**Greatest Feature of OCaml** 

## Example: Lists

```
type intlist
    = Nil
    | Cons of int * intlist

let example = Cons (1, Cons (2, Cons (3, Nil)))
```

The type **intlist** is available as the type of data which a constructor of **intlist** holds

We can use recursive ADTs to create variable—length data types

## Example: Lists

```
type intlist
    = Nil
    | Cons of int * intlist

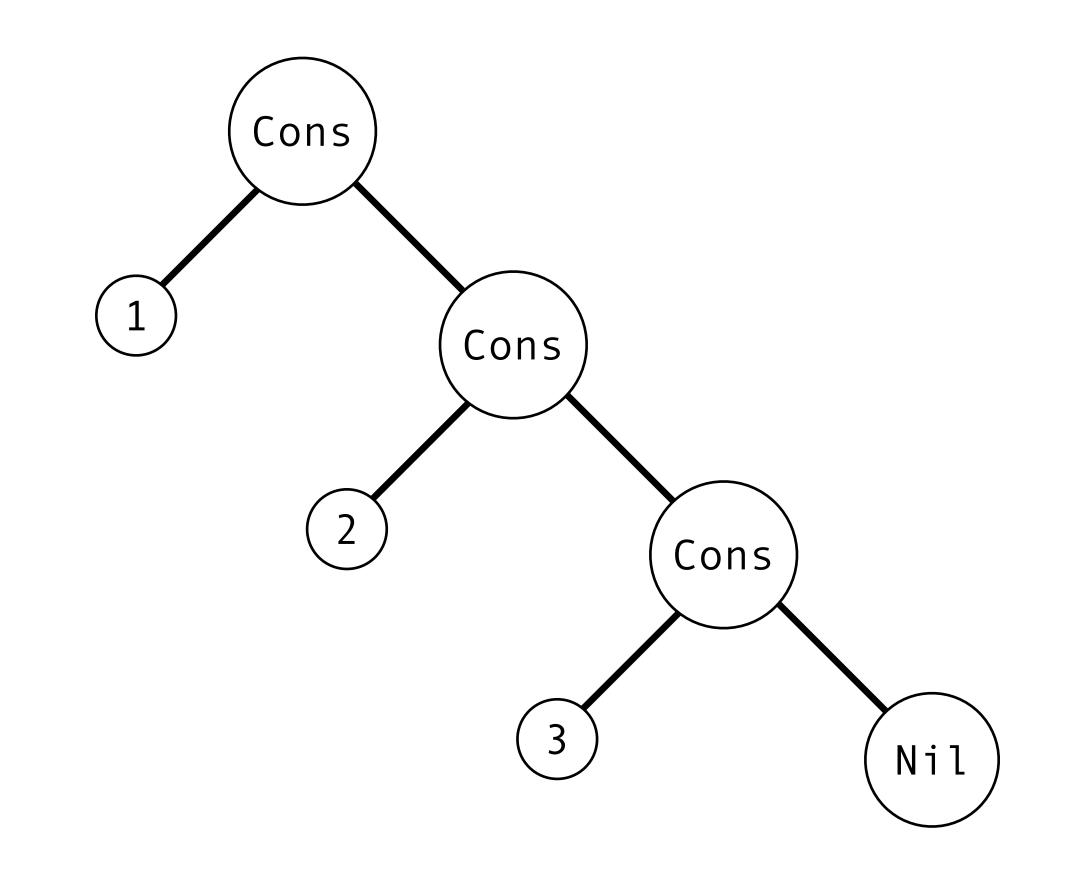

let example = Cons (1, Cons (2, Cons (3, Nil)))
```

The type **intlist** is available as the type of data which a constructor of **intlist** holds

We can use recursive ADTs to create variable—length data types

#### The Picture

```
Cons (1,
Cons (2,
Cons (3,
Nil))
```

We think of values of recursive variants as trees with constructors as nodes and carried data as leaves

# demo

(basic functions for intlist)

# Parametrized ADTs

The last piece of the puzzle: variants can be type agnostic

The last piece of the puzzle: variants can be type agnostic

This gives us a variant which is parametrically polymorphic

```
type 'a mylist
= Nil
    | Cons of 'a * 'a mylist

let e1 : int mylist = Cons (1, Cons (2, Cons (3, Nil)))
let e2 : string mylist = Cons ("1", Cons ("2", Cons ("3", Nil)))
```

The last piece of the puzzle: variants can be type agnostic

This gives us a variant which is parametrically polymorphic

```
type 'a mylist type constructor
= Nil
| Cons of 'a * 'a mylist

let e1 : int mylist = Cons (1, Cons (2, Cons (3, Nil)))
let e2 : string mylist = Cons ("1", Cons ("2", Cons ("3", Nil)))
```

The last piece of the puzzle: variants can be type agnostic

This gives us a variant which is parametrically polymorphic

## Parametric Polymorphism

```
let rev_tail (l : 'a list) : 'a list =
  let rec go acc l =
    match l with
    | [] -> acc
    | x :: xs -> go (x :: acc) xs
  in go [] l
```

## Parametric Polymorphism

```
let rev_tail (l : 'a list) : 'a list =
  let rec go acc l =
    match l with
    | [] -> acc
    | x :: xs -> go (x :: acc) xs
  in go [] l
```

This allows us to write functions which can be more generally applied (reversing a list does not depend on what's in the list)

## Parametric Polymorphism

```
let rev_tail (l : 'a list) : 'a list =
  let rec go acc l =
    match l with
    | [] -> acc
    | x :: xs -> go (x :: acc) xs
  in go [] l
```

This allows us to write functions which can be more generally applied (reversing a list does not depend on what's in the list)

Note. Because of type-inference, we rarely have to think about this

# Useful ADTs

## Options

```
type 'a option = None | Some of 'a

let head (l : 'a list) : 'a option =
  match l with
  | [] -> None
  | x :: xs -> Some x
```

## Options

```
type 'a option = None | Some of 'a

let head (l : 'a list) : 'a option =
  match l with
  | [] -> None
  | x :: xs -> Some x
```

Options are like boxes which *may* hold a value or may be empty.

## Options

```
type 'a option = None | Some of 'a

let head (l : 'a list) : 'a option =
  match l with
  | [] -> None
  | x :: xs -> Some x
```

Options are like boxes which *may* hold a value or may be empty.

This can be useful for defining functions which may not be total.

#### Aside: The Billion-Dollar Mistake

Tony Hoare calls his invention of the **null pointer** a "billion-dollar mistake"

#### OCaml doesn't have null pointers

I call it my billion—dollar mistake. It was the invention of the null reference in 1965. At that time, I was designing the first comprehensive type system for references in an object oriented language (ALGOL W). My goal was to ensure that all use of references should be absolutely safe, with checking performed automatically by the compiler. But I couldn't resist the temptation to put in a null reference, simply because it was so easy to implement. This has led to innumerable errors, vulnerabilities, and system crashes, which have probably caused a billion dollars of pain and damage in the last forty years.

#### Results

```
type ('a, 'e) myresult =
    | Ok of 'a
    | Error of 'e

let head (l : 'a list) : ('a, string) myresult =
    match l with
    | [] -> Error "[] has no first element"
    | x :: xs -> Ok x
```

A **result** is an option with additional data in the "None" case

#### Results

A **result** is an option with additional data in the "None" case

#### Results

```
type ('a, 'e) myresult =
    | Ok of 'a
    | Error of 'e

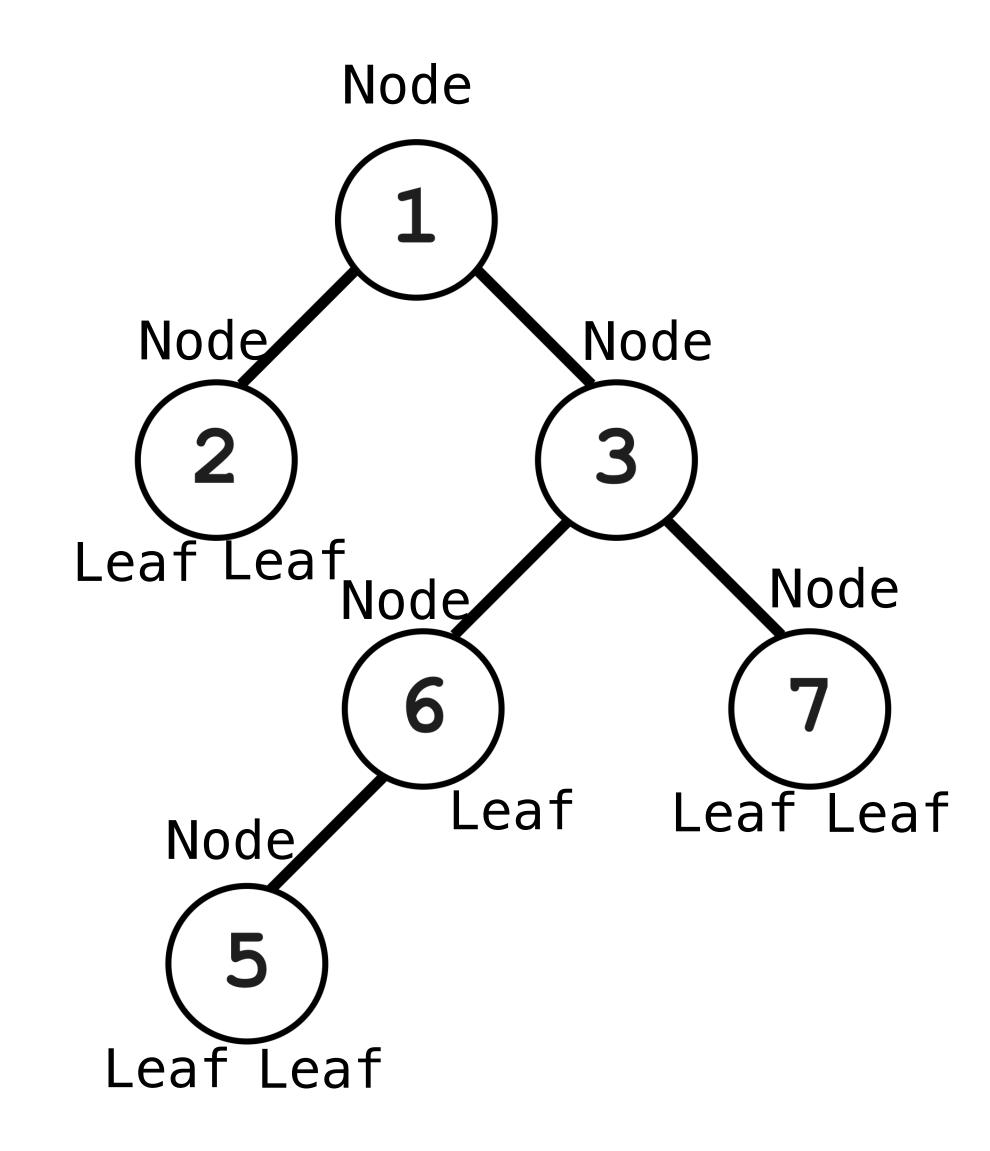

let head (l : 'a list) : ('a, string) myresult =
    match l with
    | Error message
    | [] -> Error "[] has no first element"
    | X :: xs -> Ok x
```

A **result** is an option with additional data in the "None" case

#### Trees

```
type 'a tree =
    | Leaf
    | Node of 'a * 'a tree * 'a tree
```

A tree is a leaf with a value or a node with a left or right subtree

## demo

(tree examples: size/depth & traversals)

## Lists with Multiple Element Types

Suppose we want to create a list that contains both integers and floats

- » Define a function that counts the number of integers and floats; returns a tuple/record
- » Define a function that sums up the elements of the list
- » Define a function that converts the list into a list of floats

## URM Programs

```
Recall a URM program:
» Z i: zero reg[i]
» I i: increment reg[i] register
» T I j: reg[j] <- reg[i]
» J I j k: jump to k-th instr. if reg[i] =reg[j]</pre>
```

## Summary

Tuples, records, and ADTs help us organize data and create abstract interfaces

Recursive and parametrized ADTs give us richer structure
